

An annotated checklist of the Norwegian Lonchaeidae (Diptera, Cyclorrhapha) with the description of a new species

IAIN MACGOWAN & JØRN R. GUSTAD

MacGowan, I. & Gustad, J.R. 2022. An annotated checklist of the Norwegian Lonchaeidae (Diptera, Cyclorrhapha) with the description of a new species. *Norwegian Journal of Entomology* 69, 284–303.

The status of Lonchaeidae in Norway is reviewed and a Norwegian checklist is provided for the first time listing 40 species in six genera. Whenever possible the records for each species provide details of region code, municipality, locality (grid code after the EIS-system, decimal degrees) number of individuals, sex, date, collecting method, collector and depository. Information is also provided on wider European distribution, and where known, larval habitat. A new species within the genus *Lonchaea* Fallén, 1820 namely *Lonchaea norvegica* sp. n. is described and its relationship with related species is discussed. The Norwegian fauna is compared to that of other adjacent European countries.

Key words: Diptera, Lonchaeidae, *Lonchaea norvegica*, new species, checklist, Norway.

Introduction

The Lonchaeidae is one of eight families within the superfamily Tephritoidea which also includes the Tephritidae. Worldwide the Lonchaeidae contain just over 600 species in 10 genera (MacGowan 2022) with approximately 140 species known from the Palearctic. Lonchaeidae are small-sized (body length: 3–6 mm), stout-bodied acalyprate flies, with broad wings, body usually entirely shiny blue-black, head wide and high, thorax broad, abdomen broad and flat, wing usually hyaline, haltere invariably black.

Knowledge of the family has been steadily increasing, and from a northern European perspective given impetus by the publication of a Handbook to the British Lonchaeidae (MacGowan & Rotheray 2008). Subsequently several national

checklists have been published including for Sweden (MacGowan 2015, 2020) and France (Withers & MacGowan 2014). The most recent overview of the family can be found in MacGowan & Rotheray (2021). This current checklist is the first attempt to catalogue the Norwegian fauna and set it in context with that of neighbouring north-west European countries.

Material and methods

Specimens examined came from a variety of sources, preserved in alcohol from Malaise trap samples, pinned specimens from museum collections and as fresh unpinned specimens from the contributors to this project. Whenever possible specimens were identified without dissection.

When dissection was required, specimens were micro-pinned and staged with accompanying data labels. Dissected genitalia were cleared in 10% KOH before examination and were subsequently stored in glycerol filled micro-vials attached to the specimen pin. Voucher specimens are retained in the National Museum of Scotland, Edinburgh. The taxonomic terminology used in describing the new species follows that of MacGowan & Rotheray (2021).

The collection dates of the material examined ranges from 1849 to 2021. We have tried as far as possible to examine all relevant material but we recognise that there is potentially more still to be examined, for example in unsorted Malaise trap samples. In addition, it is frequently not possible to identify many female lonchaeids to more than genus level. The records are based solely on collected material, except for six records, identified from photographs.

Acronyms used for the depositories.: Natural History Museums of Oslo (NHMO), National Museum of Scotland, Edinburgh (NMS) and University Museum of Bergen (UMB).

Description of the new species

Lonchaea Fallén, 1820

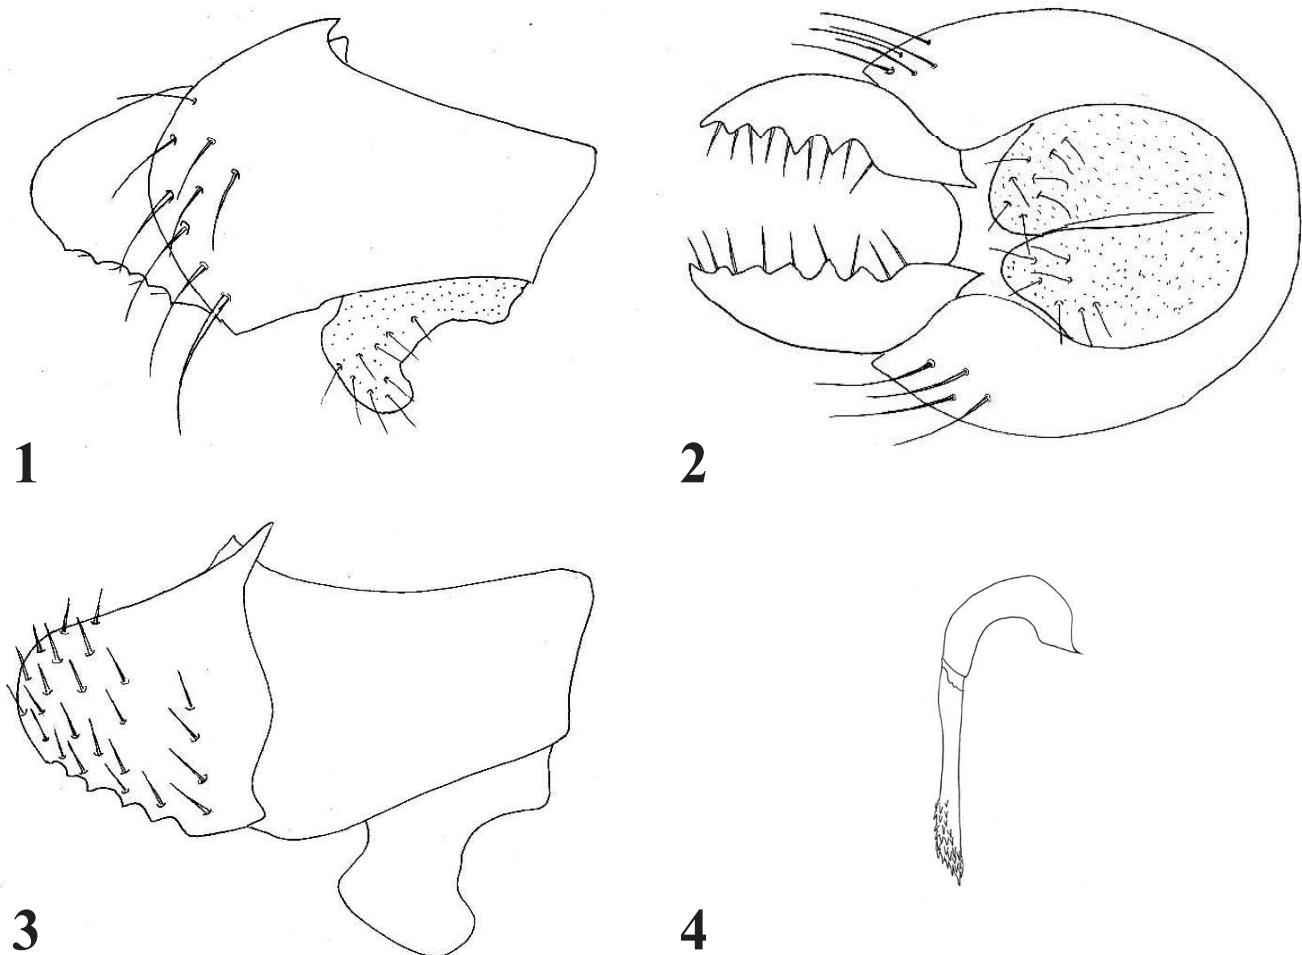

Lonchaea norvegica sp. n.

Description. Holotype ♂. Head: Eyes bare. Frons at narrowest point above lunule approximately 0.5x width of an eye heavily grey dusted, narrowing gradually from level of ocellar triangle to just above antennal bases, frontal and interfrontal setulae long, 0.6x length of orbital seta. Orbital plate black, dulled by microsculpture, bearing 4–5 setulae as long as the interfrontals. Lunule ground colour black; lunule, parafacials and face covered in dense silver-grey pollinosity. Anterior genal setulae forming a single regularly spaced row of 3–4 along mouth edge, these slightly stronger than other setulae on the genae. Palpi black, with numerous strong setae. Antennae entirely black, antennal postpedicel length to depth ratio 2.2: 1. Arista entirely black, microscopically pubescent

Thorax: Scutum sub shining blue-black, covered with light grey dusting, with a covering of long black setulae approximately 0.75x length of orbital seta. Humerus densely covered in setulae. Anepisternum grey dusted with 4 setae in a row along posterior margin, anterior setae difficult to distinguish from other numerous long setulae on the sclerite. Proepisternum with one long seta, approximately six setae on proepimeron. Katepisternum, grey dusted, a single seta located near dorsal margin a few long setulae lying anterior and posterior to this, otherwise sclerite with only rather fine, sparse setulae. Anepimeron bare. Scutellum sub-shining black, covered with grey dusting, with a pair of lateral and apical setae, the right lateral setae with an additional seta in close proximity, scutellar margin with six setulae on left, three on right side between lateral setae, six between apical setae, these approximately 0.4x as long as marginal setae, no setulae anterior to the lateral setae. Calypter white with a short whitish fringe of uniform length. Wing: length 3.6 mm, membrane slightly fumose, covered in dark microtrichia. Veins dark brown, intercostal section of wing, between insertion of Sc and R₁, short, just slightly more than length of cross vein r-m. Legs, black, short ventral fringe on tarsomeres of front, mid and hind legs golden brown, basal and second tarsomeres of hind leg brownish ventrally but this partly obscured by the covering of black setulae.

Abdomen: 1st sternite without setulae. Male terminalia (Figures 1–4): In lateral view epandrium roughly rectangular, approximately 1.5x as wide as high, bearing strong setae ventrally. Surstyli strongly sclerotised, protruding ventrally beyond shell of epandrium as a large rounded process. Cercus, membranous, relatively irregular in shape, approximately half height of epandrium; with a scattering of setulae on apical half. In posterior view surstyli strongly emarginated medially, the inner surface with approximately 25 long, thin setae, concentrated ventrally. Phallus; bi-segmented, in lateral view an inverted J-shape, basiphallus a simple curved tube, distiphallus a straight tube, slightly thickened basally and apically, apical third spiculate.

Female; unknown.

FIGURES 1–4. *Lonchaea norvegica* sp. n. Male genitalia. 1. Epandrium and associated structures, lateral view. 2. Same, posterior view. 3. Internal view of surstyli. 4. Phallus lateral view. Drawings: Iain MacGowan.

Type material: Holotype ♂. NORWAY: RY Sokndal, Skittmyr (EIS 3, N58.35048° E6.30549°) 11 June–10 July 2020, Malaise trap, leg. Jarl S. Birkeland. Coll. National Museum of Scotland, Edinburgh, specimen no. NMS-10005535.

Etymology: The specific epithet refers to the country of origin of the holotype.

Remarks: This is a long-haired, dusted species with conspicuously silver-grey face and parafacials. With the combination of bare eyes, anterior genal setae in a single row, tarsomeres partly brownish, fringes of calypteres pale, proepimeron with several setae and orbital plate with setulae it keys out in the Palearctic fauna to being near *Lonchaea subneatosa* Kovalev, 1974 and *Lonchaea freyi* Czerny, 1934 (MacGowan 2021). However, it differs from the former in that the 1st sternite is entirely bare and from the latter by having a scutellum with no marginal

setulae anterior to lateral seta and none on the disc. On dissection of the male terminalia the very distinctive bi-segmented, J-shaped phallus with a spiculate apex and the large ventrally projecting, serrated surstyli serve to easily distinguish this species from any other Palearctic *Lonchaea* species.

The Malaise trap, in which the holotype was collected, was located in an old hayfield which has not been used and harvested for approximately 20 years. On one side it is bounded by a plantation forest consisting of different species of spruce (*Picea* spp.). On the other side is a small nature reserve which contains large oak trees (*Quercus* spp.) as well as many mature aspen (*Populus tremula* L.) and a good amount of dead wood. The field itself is full of different grasses, thistles and *Rubus* sp. The margins of the hayfield on the border of the forest is quite boggy and there is a

small stream which floods the field after heavy rain (J. S. Birkeland, personal communication, June 2021). It seems most probable that this species, along with the majority of all Palearctic *Lonchaea* species, has saproxylic larvae and dead wood in the adjacent large oak and aspen trees must be suitable candidates for the larval substrate.

Annotated checklist

For each species the total number of records, the record details and relevant remarks are provided. The localities are listed from south to north, with the following details, if present: Region/geographical zone code (Endrestøl 2021), municipality, locality (grid code after the EIS-system (Endrestøl 2006), decimal degrees, number of individuals, sex, date, collecting method, collector and collection). New records to Norway are indicated by an asterisk before the species name. Previously, the Russian lonchaeid expert Vladimir Grigoryevich Kovalev, along with other entomologists (noted with their full name in the checklist) identified some of the older material in museum collections (these are marked with # after the date), these have also been re-examined and either confirmed or corrected in this checklist.

The records are listed within biogeographical zones (a modified version of the Strand-system (Endrestøl 2021)). These zones are based on the old county names, and are abbreviated as follows: Ø – Østfold; AK – Akershus; BØ – Buskerud, east; BV – Buskerud, west; VE – Vestfold; TEY – Telemark, coastal; TEI – Telemark, interior; AAY – Aust-Agder, coastal; AAI – Aust Agder, interior; VAY – Vest-Agder, coastal; VAI – Vest-Agder, interior; RY – Rogaland, coastal; RI – Rogaland, interior; HOY – Hordaland, coastal; HOI – Hordaland, interior; SFY – Sogn og Fjordane, coastal; SFI – Sogn og Fjordane, interior; OS – Oppland, south; ON – Oppland, north; HES – Hedmark, south; HEN – Hedmark, north; MRY – Møre og Romsdal, coastal; MRI – Møre og Romsdal, interior; STY – Sør-Trøndelag, coastal; STI – Sør-Trøndelag, interior; NTY – Nord-Trøndelag, coastal; NTI – Nord-Trøndelag, interior; NSY – Nordland, south coastal; NSI

– Nordland, south interior; NNV – Nordland, north coastal; NNØ – Nordland, north interior; TRY – Troms, coastal; TRI – Troms, interior; FV – Finnmark, west; FI – Finnmark, interior; FN – Finnmark, north, and FØ – Finnmark, east.

Family LONCHAEIDAE

DASIOPINAE

DASIOPINI

Dasiops Rondani, 1865

* *Dasiops facialis* Collin, 1953

Total: 4♀♀. **Records:** BØ Ringerike: Sokna (EIS 36) 1♀ 30 May 2008, L.G. Jensen leg. (UMB). RY Sokndal: Skittmyr (EIS 3, N58.35048° E6.30549°) 1♀ 21 May–11 June 2020, Malaise trap, J.S. Birkeland leg. (NMS). HOY Osterøy: Hosanger (EIS 40, N60.56832° E5.48575°) 1♀ 18 June–13 July 2020, Malaise trap, A.T. Mjøs leg. (NMS). MRY Averøy: Rokset, Kvernesveien 1283 (EIS 84, N62.9838° E7.6693°) 1♀ 7 June 2017, netted, J.R. Gustad leg. (NMS).

Remarks: An uncommon species with scattered records across western Europe. The larval habitat is unknown.

* *Dasiops laticeps* (Czerny, 1934)

Total: 1♂. **Records:** NTI Høylandet: Tverråa (EIS 107) 1♂ 11 June 1988, Malaise trap, J.O. Solem leg. (UMB).

Remarks: A rare species with a scattered distribution, occurring in Sweden, Russia Hungary and Mongolia.

* *Dasiops mucronatus* Morge, 1959

Total: 1♀. **Records:** RY Sokndal: Varåsen (EIS 3, N58.3309° E6.2629°) 1♀ 30 May–26 June 2021, Malaise trap, J.S. Birkeland leg. (NMS).

Remarks: A species more common in central and southern Europe, in the north it seems to be restricted to coastal locations. The larval habitat is unknown.

* *Dasiops occultus* Collin, 1953

Total: 1♀. **Records:** HOY Stord: Iglatjodn

myrreservat (EIS 23) 1♀ 28 June–19 July 1989, Malaise trap, L.G. Jensen leg. (UMB).

Remarks: Apparently a rather rare species with only a few records from north-western Europe.

* *Dasiops perpropinquus* Morge, 1959

Total: 1♀. **Records:** NTI Høylandet: Tverråa (EIS 107) 1♀ 6 August 1986, Malaise trap, J.O. Solem leg. (UMB).

Remarks: An uncommon species in Europe, it has been reared from larvae and pupae found under the bark of several deciduous tree species.

* *Dasiops spatirosus* (Becker, 1895) (Figure 5)

Total: 1♀1♂. **Records:** AK Enebakk: Nordre Bøler (EIS 29) 1♂ September 1996, Malaise trap, H. Breilid & H. Solberg leg. (UMB). TEY Drangedal: Laksvassmyra, Saga (EIS 10, N59.072309° E8.756784°) 1♀ 1 August 2020, collected by hand, M. Amundsen & M.A. Mjelde leg. (NMS).

Remarks: One of the more common *Dasiops* species of northern European woodlands where

the larvae develop in decaying birch.

* *Dasiops trichosternalis* Morge, 1959

Total: 1♂2♀ (1♂ dissected). **Records:** MRY Averøy: Rokset, Kvernesveien 1283 (EIS 84, N62.9838° E7.6693°) 1♂ 10 June 2020, netted, J.R. Gustad leg. (NMS). NTI Høylandet: Tverråa (EIS 107) 1♀ 9 July 1986, 1♀ 13 August 1986, Malaise trap, J.O. Solem leg. (UMB).

Remarks: An uncommon species. The larval habitat is unknown.

LONCHAEINAE

EAROMYIINI

Protearomyia McAlpine, 1962

* *Protearomyia nigra* (Meigen, 1826)

Total: 2♂♂. **Records:** MRY Averøy: Rokset, Kvernesveien 1283 (EIS 84, N62.9838° E7.6693°) 1♂ 12 June 2020, netted, J.R. Gustad leg. (NMS). MRI Molde: Eikesdal, Finnset

FIGURE 5. *Dasiops spatirosus* (Becker, 1895). The second record from Norway, a female, from Drangedal 1 August 2020. Photo: Morten Angard Mjelde.

(EIS 78, N62.4232° E8.3235°) 1♂ 20 June 2021, netted, J.R. Gustad leg. (NMS).

Remarks: *P. nigra* seems to be the only member of this genus to occur at more northern latitudes although a further two species occur in southern Sweden. The larvae are considered to develop in the stems of herbaceous plants. 10 additional female specimens of *Protearomyia* ssp. were collected from Ø, AK, RY, SFI, MRY and MRI but these cannot confidently be assigned to a species.

Chaetolonchaea Czerny, 1934

Chaetolonchaea dasyops (Meigen, 1826)

Total: 3♀♀, 1 not sexed. **Records:** AK Bærum: Fornebu, Lilløypllassen (EIS 28) 1 ex 18 May 2008, photo, J.M. Mjelde leg. VE Larvik: Nevlungstrand (EIS 18, N58.968° E9.8450°) 1♀ 7 June 2010, netted, G.E.E. Søli leg. (NHMO). RY Sokndal: Varåsen (EIS 3, N58.3309° - E6.2629°) 1♀ 3-30 April 2021, 1♀ 30 May-26 June 2021, Malaise trap, J.S. Birkeland leg. (NMS).

Remarks: This is the less common of the two species of *Chaetolonchaea* found in Norway, it usually found in meadow habitats where the larvae, as with all *Chaetolonchaea* species, are thought to develop in bulbs and tubers.

* *Chaetolonchaea pallipennis* (Zetterstedt, 1855)

Total: 7♀♀2♂♂, 1 not sexed. **Records:** Ø Råde: Tasken N (EIS 20) 1♀ 2–24 June 1995, Malaise trap, J.I.I. Båtvik & O. Hanssen leg. (NHMO). AK Oslo: Tøyen, botanisk have, 1♀ 8 July 1850#, J.H.S. Siebke leg. (NHMO), previously published as *L. dasyops* by Siebke (1877). Oslo: Tøyen (EIS 28) 1♀ no date, J.H.S. Siebke leg. (NHMO) (could be the second individual given as ♂, in Siebke (1877)). Bærum: Ostøya (EIS 28, N59.868° E10.571°) 1 imago 31 May 1984#, L.G. Jensen leg. (UMB). AK? Labels not readable to current location 1♀ 16 June 1849, J.H.S. Siebke leg. (NHMO). BØ Asker: Hurum, Tofteholmen (EIS 19) 1♀ 28 May–7 July 1991, Malaise trap, L.O. Hansen leg. (NHMO). VE Larvik: Mølen (EIS 11, N58.96812° E9.84192) 1♀ 31 May 2021, netted, M. Amundsen & M.A. Mjelde leg. (NMS). TEY Bamble: Langøya

(EIS 11) 1♂ 2–28 May 1991, Malaise trap, L.O. Hansen leg. (NHMO). Kragerø: Portør (EIS 11, N58.791206° E9.388083°) 1♂ 16 May 2021, M.A. Mjelde leg. (NMS). ON Vang: Vennis, Døtten (EIS 52, N61.1660° E8.4904°) 1♀ 27 June 2021, netted, J.R. Gustad leg. (NMS).

Remarks: First record is from 1849. This is the smaller and more common of the two species, it may be more tolerant of colder temperatures.

Earomyia Zetterstedt, 1842

Earomyia lonchaeoides Zetterstedt, 1848

Total: 2♀♀1♂. **Records:** Ø Halden (EIS 12) 1♀ 6 May–9 June 1986, Malaise trap, F. Midtgård leg. (UMB). AK Frogner: Drøbak, Tomters Øvre vei 10 (EIS 28, N59.69950° E10.64576°) 1♀ 1 May 2013, photo, J.R. Gustad leg. TEY Drangedal: Neslandsvatn, Løbbedalen 76 (EIS 11, N58.97625° E09.16715°) 1♂ 19 March 2019, photo, M.A. Mjelde leg.

Remarks: The two latter records were previously published in Gustad & MacGowan (2020). This can be a very common species in European woodlands but its early spring emergence may lead to a paucity of records. The larval habitat is unknown.

LONCHAEINI

Lonchaea Fallén, 1820

Lonchaea affinis Malloch, 1920

Total: 58♀♀15♂♂, 15 not sexed. **Records:** Ø Halden: Strupe (EIS 12, N59.138° E11.371°) 1 imago 5 June 1967#, anonymous leg. (UMB). Indre Østfold: Eidsberg, Mysen, Åsen (EIS 29) 1♀ 21 June 2012, S.E. Eriksen & O. Sørlibræten leg. (NHMO). Krokstad bruk (EIS 29) 1♂ 15 June 2013, O. Sørlibræten leg. (NHMO). AK Oslo: Ryen, Ryenberg 1♀ 23 June 1849, J.H.S. Siebke leg. (NHMO), previously listed as *L. albitarsis* Zetterstedt, 1837 by Siebke (1877). Hasle (EIS 28) 1♀ 17 August 1851, J.H.S. Siebke leg. (NHMO), previously listed as *L. albitarsis* by Siebke (1877). Ljanselva, Liadalen (EIS 28, N59.848° E10.792°) 1♀ 25 June–5 July 2010, Malaise trap, M. Steinert & S. Steinert leg. (NHMO). Ljanselva, Urskogen

(EIS 28, N59.854° E10.818°) 1♀ 25 June–5 July 2010, Malaise trap, M. Steinert & G.E.E. Søli leg. (NHMO). Østensjøvannet, Bogerudmyra (EIS 28, N59.87° E10.83°) 1♀ 18 June 2012, netted, G.E.E. Søli leg. (NHMO). Sørkedalen, Svartorsætra (EIS 28, N60.026° E10.646°) 1♀ 6–12 June 2018, Malaise trap, H. Elven leg. (NHMO). Lørenskog: Losby (EIS 29) 2♀♀ 27 June–1 August 1991, Malaise trap, B. Økland leg. (NHMO). Ullensaker: Sessvollmoen, Aurtjernet V (EIS 29) 1♀ 30 June–12 August 2008, Malaise trap, L.O. Hansen leg. (NHMO). Nesodden: Rørtjern (EIS 28, N59.811° E10.679°) 1♀ 2 July–1 August 2010, Malaise trap, O.J. Lønnve leg. (NHMO). **BØ** Kongsberg: Jondalen (EIS 27) 1 imago 20 June 1983, B.A. Sagvolden leg. (NHMO). Skartveit leg. (UMB).

Remarks: First record is from 1849. This species has previously been known and published as *Lonchaea laxa* Collin, 1953, but MacGowan (2019) recognised *L. laxa* as a junior synonym of *Lonchaea affinis*. The Sigdal material was originally determined as *L. laxa* by John Skartveit and published as such in Thunes *et al.* (2004). This is one of the most common Scandinavian lonchaeids with the larvae breeding in the decaying wood of a range of coniferous trees

Lonchaea albatarsis Zetterstedt, 1837

Total: 5♀♀7♂♂. **Records:** **AK** Oslo: Lutdalen (EIS 28) 1♂ 28 June–5 July 1990, Malaise trap, M. Falck leg. (NHMO). **AAI** Evje og Hornnes: Kjetså (EIS 25, N59.54396° E7.75594°) 1♀ 2–16 June 2020, Malaise trap, L. Breistøl leg. (UMB). **OS** Østre Toten: Balke kirke (EIS 45, N60.668322° E10.951030°) 1♂ 25 July 2021, M.A. Mjelde leg. (NMS).

Remarks: First record from 1992. A very widespread species in the western Palearctic, most common in southern and central Europe and reaching its northern limit in Scandinavia.

Comparison with the faunas of other Scandinavian countries and the British Isles.

Diptera checklists which include Lonchaeidae, are already available for the British Isles, Denmark, Sweden and Finland and reference to these allows the Norwegian fauna to be placed in context with these neighbouring countries. Kahanpää & Winqvist (2014) lists a total of 41 species, with an additional three unconfirmed species, as occurring in Finland. Since that time one of the unconfirmed species *Lonchaea difficilis* Hackman, 1956 has

been confirmed by MacGowan (2016). In addition, *Proteromyia jonesi* MacGowan & Reimann, 2021 was added by MacGowan & Reimann (2021) and *Silba fumosa* was added from photographs identified on iNaturalist (<https://www.inaturalist.org/observations/89757748>). A further nine species; *Dasiops hennigi*, *L. bruggeri*, *L. contigua*, *L. contraria*, *L. gordodkovi*, *L. hyalipennis*, *L. obscuritarsis*, *L. postica* and *P. withersi* are listed in the Finnish biodiversity database (Suomen Lajitietokeskus, 2022) bringing the Finnish total to 53 species.

For the British Isles the Diptera checklist is regularly updated and is available online (MacGowan 2022). As of October 2022, this includes 51 species of Lonchaeidae. The Swedish Lonchaeidae checklist was updated in 2015 and 2020. The Swedish fauna has been intensively studied as a result of the Swedish Malaise trap project and other initiatives and a result the number of recorded species at 66 is the highest of the countries considered here. In Denmark 33 confirmed species were included in the Diptera checklist of 2001 (MacGowan 2001) with *Dasiops spatiiosus* (Becker, 1895) added by MacGowan (2005) and *Earomyia argenta* MacGowan, 2020 by MacGowan (2020) giving a total of 35 species.

Discussion

This checklist confirms the presence of 40 species of Lonchaeidae in Norway, one of which is new to science and a further 32 species which are new national records. Of the previous nine published Norwegian lonchaeid records there are seven species which we include in this present checklist. Of the other two published records *Lonchaea laticornis* Meigen, 1826 is now considered to represent a complex of species and the original record of *Lonchaea palposa* Zetterstedt, 1847 was based on an incorrect identification and as no further specimen has been recorded it is not included.

Table 1 would illustrate that there are still many other species which could be potentially found in Norway. In particular the discovery of a species new to science indicates that there is

TABLE 1. The Lonchaeid fauna of Scandinavia, Finland and the British Isles. Present known distribution. A total of 76 species are recorded.

still much to be discovered about the Norwegian lonchaeid fauna.

The lonchaeid fauna of Norway is in general similar to that of the other four countries with which it is compared in Table 1. For example, all of the Norwegian species apart from *Dasiops trichosternalis* and the newly described *Lonchaea norvegica* are also found in Sweden. Differences in the number of species recorded in each country are most likely a result of collecting intensity.

The most obvious comparison is that with Norway's closest neighbour Sweden which, with a fauna of 66 species, is one of the best studied in Europe. This is due in part to the large amount of material collected by initiatives such as the Swedish Malaise Trap Project (SMTP). Southern Sweden hosts some species at the northern edge of their European range such as *Chaetolonchaea brevipilosa* and *Protearomyia rameli* which have not been recorded from Norway at present. In terms of species abundance MacGowan (2015) reported *Lonchaea affinis* as being the most common species in SMTP samples and this corresponds with our findings for Norway where it is only second in terms of records to *Lonchaea chorea*. The latter species favours anthropogenic habitats and is consequently often well represented in collections. Woodland species such as *Lonchaea deutschi* and *L. sylvatica* are also important elements of the fauna in both countries. *Lonchaea fugax*, which was the most common species obtained in rearing surveys in Sweden (MacGowan, 2015) is also an important constituent of the fauna in both countries.

Our experience from the present study has shown that combining the resources of amateur entomologists and nature photographers with those of museum collections and taxonomic specialists can be very effective when undertaking a project such as this. As a result, over a period of only a few years, we have increased the known lonchaeid fauna of Norway from seven to 40 species.

Further studies on the family could potentially focus on biology, habitat preferences, catching methods and flight period. At present little work has been undertaken combining classic identification with DNA barcoding. This has been

used with success for other groups, revealing both discoveries and options for further research.

Acknowledgements. We thank the following: NHMO, UMB and Museum Stavanger for allowing us to study their specimens, and the latter for allowing the National Museums of Scotland to retain specimens as a reference collection; Steffen Roth and Geir Einar Ellefsen Søli for arranging specimen loans from UMB and NHMO; respectively; Morgan Amundsen, Jarl S. Birkeland, Halvard Hatlen, Terje Jonassen, Morten Angard Mjelde, Alf Tore Mjøs, Kåre Solheim and Geir Ørsnes for providing specimens; Terje Jonassen for sorting material from the Stavanger Museum Malaise project (MUST Malaise); Kaare Aagaard for information on whom is to be credited for the Malaise samples in Høylandet; Morten Angard Mjelde and Kåre Solheim for use of their photographs in this article. Without this help and enthusiasm of all these partners and individuals this study would not have been possible.
