Layout

① Introduction

- Characteristics of the airlines industry

- A definition and some numbers

- A historical perspective

- The main components of RM

② Overbooking

- Overview of the problem

- Initial model of Beckmann (1958)

- Dynamic problem of Rothstein (1971)

③ Seat inventory control

- Littlewood (1972): from overbooking to SIC

- Nested fare class

- Origin-Destination Fare (ODF)

- Network revenue management

- Bid-Price control for Network Revenue Management

④ Evidences of RM

- The example of Ryanair

④ Evidences of RM

The example of Ryanair

Characteristics of the airlines industry

- We can not “store” any seat: they are only available at the departure. Each empty seat is a revenue loss.
- The number of seats in a airplane is fixed.
- The cost of a flight is largely independent of the numbers of occupied seats.
- People who make their reservations early are more price sensitive: we can segment market by the *time of purchase*.

The motivation of Revenue Management

Given that capacity and cost are fixed for each flight, how to increase the profitability?

Increasing revenue by segmenting market

Characteristics of the airlines industry

- We can not “store” any seat: they are only available at the departure. Each empty seat is a revenue loss.

A definition and some numbers

Definition (Smith et al., 1992)

A [...] description of yield management (YM) as it applies to airlines is the control and the management of reservations inventory in a way that increases (maximizes, if possible) company profitability, given the flight schedule and structure.

- American Airlines (AA) estimates the annual revenue contribution of YM around \$500 millions at the beginning of 90's
- \$8.4 billions benefice for the airline industry in 2011 (IATA, 2012)
- Operating margin is on average only 1.64% in US airlines (Bureau of Transportation Statistics, 2011)
- A medium-sized airline operates 1000 flight legs, 10 booking classes and its reservation system accepts booking 330 days in advance (Barnhart et al., 2003).

The example of Ryanair

A historical perspective: the example of AA

- 1966 Implementation of SABRE (semi-automated business research environment) a centralized and computerized reservation system at AA
- 1977 Introduction of *Super Saver* discount fare at AA
- 1978 Airline Deregulation Act in USA that deregulates schedules and prices. It increases the number and the variety of discount fares. Besides, airlines began offering connecting services, using centrally located airports as hubs.
- 1981 First Low Cost Carriers (PEOPLExpress, . . .)
- 1985 Introduction of *Ultimate Super Saver* at AA
- 1988 Implementation of new Revenue Management System (RMS) called DINAMO (Dynamic Inventory Optimization and Maintenance Optimizer) that manages network effects with *virtual nesting*.

Main problematics of RM in airlines

Overbooking

No-show rates average 5%-25% of final predeparture bookings. Hence, overbooking is a trade off between revenue losses of *spoiled seats* and costs of *denied boarding*.

Seat inventory control

SIC is a trade off between revenue losses of excessive number of low-fare seats and empty seats. Models go from the initial *expected marginal seat revenue* (EMSR) to *optimal booking limits* by *Origin-Destination-fare (ODF) control*.

Pricing

There is a natural duality between price and seat allocation decisions (McGill and Van Ryzin, 1999). *Bid-prices* can replace multiple booking limits and complex nesting schemes.

Main problematics of RM in airlines

Overbooking

No-show rates average 5%-25% of final predeparture bookings. Hence, overbooking is a trade off between revenue losses of *spoiled seats* and costs of *denied boarding*.

Seat inventory control

Overview of overbooking

Dilemma of overbooking

Overbooking is the fact of overselling seats to compensate losses from cancellations and *no-shows*. But *denied boarding* has a cost as well as *spoiled seats*.

This Civil Aeronautics Board recognized and controlled this practice.

- Booking are accepted up to 330 days in advance
- Cancellations or new reservations can occur during this period
- Even with a full booked flight, *no-shows* can lead to empty seats
- *Standby* may appear at flight time
- It may possible to reassign excess passengers

Initial model of Beckmann (1958)

A simple model

The model of Beckmann (1958) yields the *booking level* for reservations that minimizes expected costs.

$$a \int_0^{x-c} (x - \kappa - c) dP(\kappa | x) + b \int_{x-c}^x \mathcal{N}(\kappa) dP(\kappa | x) \quad (1)$$

- The *booking level*, x , is given
- Model assume a unique fare
- Model does not give any *probability of denied boarding*.

Initial model of Beckmann (1958)

A simple model

The model of Beckmann (1958) yields the *booking level* for reservations that minimizes expected costs.

$$a \int_0^{x-c} (x - \kappa - c) dP(\kappa | x) + b \int_{x-c}^x \mathcal{N}(\kappa) dP(\kappa | x) \quad (1)$$

Littlewood (1972): from overbooking to SIC

Overbooking: When prices were regulated, maximizing profit was equivalent to maximize the number of passengers carried by flight.

Seat Inventory Control: When prices are unregulated, maximizing profit leads also to optimize mix of fares.

Single leg Seat Inventory Control

Littlewood (1972) proposed to protect p high-fare seats so that the probability of *denial boarding* for high-fare is bounded by $Pr(D_{high} \geq p)$. The Expected Marginal Seat Revenue (EMSR) rule is the following:

$$f_{low} \geq f_{high} Pr(D_{high} \geq p) \quad (2)$$

Littlewood (1972): from overbooking to SIC

The example of Ryanair

Network revenue management

A leg-based seat inventory control system can not discriminate between AB and AC booking on the AB leg: it does not consider itinerary.

Optimal seat allocation with ODF (Curry, 1990)

Curry (1990) proposed the following program to maximize the expected revenue for all itineraries j .

$$\max_A \sum_j \sum_k R_{jk}(A_{jk}) \quad (3)$$

subject to

$$\sum_j \sum_{k \in i} A_{jk} \leq C_i \quad (4)$$

Network revenue management

Bid-Price control for Network Revenue Management

Bid-price

We accept a fare only when R exceeds the *opportunity cost* of the reduction in leg capacities.

$$u_{jt}(R_j, X_j) = \begin{cases} 1 & R_j \geq \sum_j \pi_j(X_j) \\ & X_j \leq C_t \\ 0 & \text{otherwise} \end{cases}$$

- Similar to dual prices of (4).
- Suboptimal when $\pi_j \geq \sum_{i \in J} \pi_i$
- How computing π (LP, Prorated EMSR, ...)

Bid-Price control for Network Revenue Management

Bid-price

We accept a fare only when R exceeds the *opportunity cost* of the reduction in leg capacities.

Bid-Price control for Network Revenue Management

Bid-price

We accept a fare only when R exceeds the *opportunity cost* of the reduction in leg capacities.

$$u_{jt}(R_j, X_j) = \begin{cases} 1 & R_j \geq \sum_j \pi_j(X_j) \\ & X_j \leq C_t \\ 0 & \text{otherwise} \end{cases}$$

- Similar to dual prices of (4).
- Suboptimal when $\pi_j \geq \sum_{i \in j} \pi_i$
- How computing π (LP, Prorated EMSR, ...)

Layout

① Introduction

- Characteristics of the airlines industry
- A definition and some numbers
- A historical perspective
- The main components of RM

② Overbooking

- Overview of the problem
- Initial model of Beckmann (1958)
- Dynamic problem of Rothstein (1971)

③ Seat inventory control

- Littlewood (1972): from overbooking to SIC
- Nested fare class
- Origin-Destination Fare (ODF)
- Network revenue management
- Bid-Price control for Network Revenue Management

④ Evidences of RM

- The example of Ryanair

Average price and demand
